So far, we have discussed discrete-time Markov chains in which the chain jumps from the current state to the next state after one unit of time. That is, the time that the chain spends in each state is a positive integer. It is equal to 1 if the state does not have a self-transition

$$\mathbb{P}_{i,i} = 0,$$

or it is a

$$\textit{Geometric}(1 - \mathbb{P}_{i,i})$$

random variable if  $\mathbb{P}_{i,i} > 0$ . Here, we would like to discuss continuous-time Markov chains where the time spent in each state is a continuous random variable.

# CTMC

Dan Zhu

A Continuous Time Markov Chain makes transitions from state to state **at any instant of time rather than at fixed intervals**, independent of the past,: once entering a state remains in that state, independent of the past, for an **exponentially** distributed amount of time before changing state again.

A gas station has a single pump and no space for vehicles to wait (if a vehicle arrives and the pump is not available, it leaves). Vehicles arrive to the gas station following a Poisson process with a rate of  $\lambda = 3/20$  vehicles per minute, of which 75% are cars and 25% are motorcycles. The refuelling time can be modelled with an exponential random variable with mean 8 minutes for cars and 3 minutes for motorcycles, that is, the services rates are  $\mu_c = 1/8$  cars and  $\mu_m = 1/3$  motorcycles per minute respectively.

Can we model my son's health condition via a CTMC? If yes, how?

## Definition (Markov jump process)

*Let  $X = (X_t)_{t \geq 0}$  be a family of random variables taking values in a finite or countable state space  $S$ , which we can take to be a subset of the integers.  $X$  is a continuous-time Markov chain (CTMC) if it satisfies the markov property*

$$P(X_{t_n} = x_n | X_{t_1} = x_1, \dots, X_{t_{n-1}} = x_{n-1})$$

The process is time-homogeneous if the conditional probability does not depend on the current time, so that:

$$P(X_{t+s} = j | X_s = i) = P(X_t = j | X_0 = i), s > 0.$$

We will consider only time-homogeneous processes in this lecture.

More specifically, we will consider a random process  $\{X_t, t \in [0, \infty)\}$ . If  $X_0 = i$ , then  $X_t$  stay in state  $i$  for a random amount of time, say  $\tau_1$ , where  $\tau_1$  is a continuous random variable. At the time  $\tau_1$ , the process jumps to a new state  $j$  and will spend a random amount of time  $\tau_2$  in that state, and so on. As it will be clear shortly, the random variables  $\tau_1, \tau_2, \dots$  have an exponential distribution. In this cases, the  $T_i = \sum_{j=1}^i \tau_j$  denote the time of the jump.<sup>1</sup>

---

<sup>1</sup>Sometimes,  $W_i$  is used to denote the waiting times.

$$Q_{NESS} = \begin{pmatrix} -1 & 1/3 & 2/3 \\ 2/3 & -1 & 1/3 \\ 1/3 & 2/3 & -1 \end{pmatrix}$$

# Exponential Holding time

Dan Zhu

Our first question of continuous-time time-homogeneous Markov chains, and one whose answer will eventually lead to a general construction/simulation method, is:

How long will this process remain in a given state, say  
 $X_0 = i \in \mathbb{S}$

$$\begin{aligned} & \mathbb{P}(T_1 > s + t | T_1 > s) \\ &= \mathbb{P}(X_v = i, \text{ for } v \in [0, s + t] | X_v = i, \text{ for } v \in [0, s]) \\ &= \mathbb{P}(X_v = i, \text{ for } v \in [s, s + t] | X_v = i, \text{ for } v \in [0, s]) \\ &= \mathbb{P}(X_v = i, \text{ for } v \in [s, s + t] | X_s = i) \text{ Markov} \\ &= \mathbb{P}(X_v = i, \text{ for } v \in [0, t] | X_0 = i) \text{ time-homogeneity} \\ &= \mathbb{P}(T_1 > t | T_1 > 0) \end{aligned}$$

The memoryless property implies Exponential Distribution.

Let's define the transition probability  $\mathbb{P}_{i,j}^{(s,t)}$

$$\begin{aligned}\mathbb{P}_{ij}^{(s,t)}(t) &= P(X_t = j | X_s = i) \quad \text{for all } 0 < s < t < \infty \\ &= P(X(t-s) = j | X(0) = i), \text{ if time inhomogeneous}\end{aligned}$$

This can also be written in its matrix form

$$\mathbb{P}(t) = \begin{bmatrix} \mathbb{P}_{11}(t) & \mathbb{P}_{12}(t) & \dots & \mathbb{P}_{1r}(t) \\ \mathbb{P}_{21}(t) & \mathbb{P}_{22}(t) & \dots & \mathbb{P}_{2r}(t) \\ \vdots & \vdots & \vdots & \vdots \\ \mathbb{P}_{r1}(t) & \mathbb{P}_{r2}(t) & \dots & \mathbb{P}_{rr}(t) \end{bmatrix}.$$

The Chapman-Kolmogorov Equation for the time homogeneous case,<sup>2</sup> is given by

$$\mathbb{P}_{i,j}^{(t+s)} = \sum_{k \in \mathbb{S}} \mathbb{P}_{i,k}^{(s)} \mathbb{P}_{k,j}^{(t)}$$

In the matrix format, is

$$\mathbb{P}^{(t+s)} = \mathbb{P}^{(s)} \mathbb{P}^{(t)}$$

---

<sup>2</sup> $\mathbb{P}_{i,j}^{(t)} = \mathbb{P}(X_t = j | X_s = i) = \mathbb{P}(X_{t-s} = j | X_0 = i)$  only depends the lag 

## The Chapman Kolmogorov Equations in continuous time

$$\mathbb{P}^{(t+s)} = \mathbb{P}^{(t)}\mathbb{P}^{(s)},$$

This is the direct analog of the discrete-time result. Just a note on terminology: in the discrete-time case, we called the matrix  $\mathbb{P}^{(n)}$  the  $n$ -step transition probability matrix. Because there is no notion of a time step in continuous time, we call  $\mathbb{P}^{(t)}$  the matrix transition probability function. Note that it is a matrix-valued function of the continuous variable  $t$ .

# Transition rates

We assume that for the homogeneous and inhomogeneous case

$$\mathbb{P}_{i,j}^{(t)}|_{t=0} = \mathbb{P}_{i,j}^{s,s+t}|_{t=0} = \delta_{i,j} = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$$

## Definition (Transition rate)

*Given the transition matrix  $\mathbb{P}^{(t)}$  and  $\mathbb{P}^{(s,t)}$  for a homogeneous and an inhomogeneous Markov chain respectively, the generator matrix  $A$  and  $A(s)$  such that their  $i, j$ th element is the transition rate from state  $i$  to  $j$*

$$\mu_{i,j} = \frac{d}{dt} \mathbb{P}_{i,j}^{(t)}|_{t=0} = \lim_{t \rightarrow 0} \frac{\mathbb{P}_{i,j}^{(t)} - \delta_{i,j}}{t}$$

$$\mu_{i,j}(s) = \frac{\partial}{\partial t} \mathbb{P}_{i,j}^{(s,t)}|_{t=s} = \lim_{h \rightarrow 0} \frac{\mathbb{P}_{i,j}^{(s,s+h)} - \delta_{i,j}}{h}$$

The sum of each row of  $A$  is zero, i.e.

$$\mu_{i,i} = - \sum_{j \neq i} \mu_{i,j}.$$

This is simply because

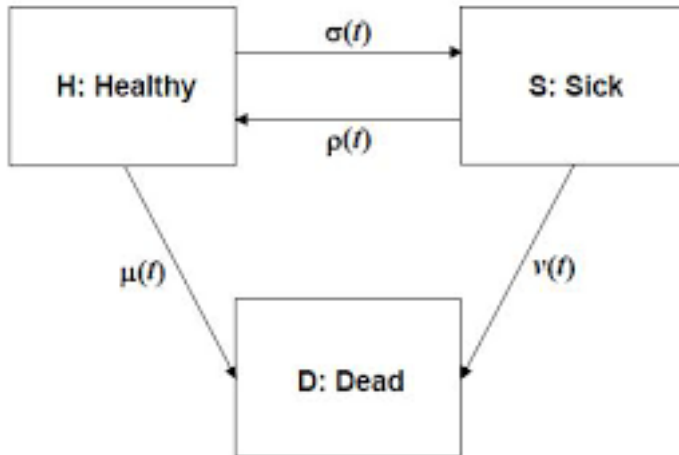

$$\sum_{j \in \mathbb{S}} \mathbb{P}_{i,j}^{(t)} = 1.$$

The same result also holds for the time inhomogeneous case.

Consider the state of a person,  
 $\mathbb{S} = \{\text{Healthy}, \text{Sick}, \text{Dead}\}$  with a constant transition such  
that

$$\mu_{H,S} = \sigma, \quad \mu_{H,D} = \mu, \quad \mu_{S,H} = \rho, \quad \mu_{S,D} = \nu.$$

The resulting transition is of

$$A = \begin{bmatrix} -\mu - \sigma & \sigma & \mu \\ \rho & -\rho - \nu & \nu \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

# Transition Diagram

Dan Zhu

We can similar try transition diagram for continuous time Markov process, i.e.

$$A = \begin{bmatrix} -5 & 5 & 0 \\ 1 & -2 & 1 \\ 3 & 1 & -4 \end{bmatrix}, \quad (1)$$

## Definition

A **differential equation** is an equation involving derivatives of an unknown function and possibly the function itself as well as the independent variable.

## Example

$$y' = \sin(x), \quad (y')^4 - y^2 + 2xy - x^2 = 0, \quad y'' + y^3 + x = 0$$

1<sup>st</sup> order equations

2<sup>nd</sup> order equation

## Definition

The **order** of a differential equation is the highest order of the derivatives of the unknown function appearing in the equation

In the simplest cases, equations may be solved by direct integration.

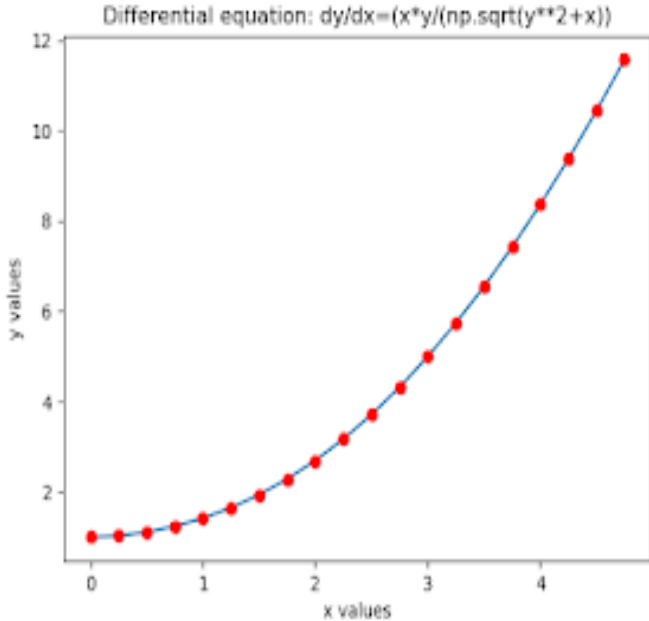

## Examples

$$y' = \sin(x) \Rightarrow y = -\cos(x) + C$$

$$y'' = 6x + e^x \Rightarrow y' = 3x^2 + e^x + C_1 \Rightarrow y = x^3 + e^x + C_1x + C_2$$

Observe that the set of solutions to the above 1<sup>st</sup> order equation has 1 parameter, while the solutions to the above 2<sup>nd</sup> order equation depend on two parameters.

Mika Seppälä: Differential Equations

# The Forward Differential Equation

The FDE is a powerful tool for solving the transition matrix, as it constructs simultaneous differentiations. For two dimensional case,

$$A = \begin{bmatrix} -a & a \\ b & -b \end{bmatrix}$$

Hence

$$\frac{d}{dt}\mathbb{P}_{1,2}^{(t)} = a\mathbb{P}_{1,1}^{(t)} - b\mathbb{P}_{1,2}^{(t)} = a - (a+b)\mathbb{P}_{1,2}^{(t)}$$

The solution of the above ODE is

$$\mathbb{P}_{1,2}^{(t)} = \frac{a}{a+b} + C \exp^{-(a+b)t} \text{ with } \mathbb{P}_{1,2}^{(0)} = 0$$

hence

$$\mathbb{P}_{1,2}^{(t)} = \frac{a}{a+b}(1 - \exp^{-(a+b)t})$$

## Theorem

*In a simple time homogeneous case, we have the FKE and BKE as*

$$\frac{\partial}{\partial t} \mathbb{P}^t = \mathbb{P}^t A \text{ and } \frac{\partial}{\partial t} \mathbb{P}^t = A \mathbb{P}^t.$$

*Using matrix exponential, we have the solution*

$$\mathbb{P}^t = \mathbb{P}^0 \exp^{tA} \text{ where } \exp Q = \sum_{i=0}^{\infty} \frac{Q^i}{i!}.$$

Though the backward and forward equations are two different sets of differential equations, with the above boundary condition they have the same solution, given by

$$\mathbb{P}^t = \exp^{tA} = \sum_{i=0}^{\infty} \frac{t^i A^i}{i!} = \mathbb{I} + tA + \frac{t^2}{2} A^2 + \dots$$

We can take derivatives

$$\frac{d}{dt} \mathbb{P}^t = \sum_{i=0}^{\infty} \frac{t^{i-1} A^i}{(i-1)!} = A + tA^2 + \frac{t^2}{2} A^3 \dots = A(\mathbb{I} + tA + \frac{t^2}{2} \dots) A^2 + \dots$$

Hence, this is  $\frac{d}{dt} \mathbb{P}^t = A \mathbb{P}^t = \mathbb{P}^t A$ .

# Computing Matrix Exponentials

Dan Zhu

Suppose that  $A$  is an  $n \times n$  matrix with  $n$  distinct eigenvectors. Then, letting  $D$  be a diagonal matrix consisting of the eigenvalues of  $A$ , we can decompose  $A$  into

$$A = QDQ^{-1}$$

where  $Q$  consists of the eigenvectors of  $A$  (ordered similarly to the order of the eigenvalues in  $D$ ). In this case, we get the very nice identity

$$\exp^{At} = \sum_{i=0}^{\infty} \frac{t^i (QDQ^{-1})^i}{i!} = Q \sum_{i=0}^{\infty} \frac{D^i}{i!} Q^{-1} = Q \exp^{Dt} Q^{-1}.$$

where  $\exp^{Dt}$ , because  $D$  is diagonal, is a diagonal matrix with diagonal elements  $\exp^{\lambda_i t}$  where  $\lambda_i$  the  $i$ th eigenvalue.

*For a continuous markov process  $X_t$  with  $\mathbb{P}(t)$ , a probability distribution  $\pi$  on  $\mathbb{S}$  is a vector with  $\pi_i \in [0, 1]$  and*

$$\sum_{i \in \mathbb{S}} \pi_i = 1$$

*is said to be stationary distribution of  $X_t$  is*

$$\pi = \pi \mathbb{P}(t) \text{ for all } t > 0.$$

## Example

Dan Zhu

Consider a continuous markov process with two states with transition matrix as

$$P(t) = \begin{bmatrix} \frac{1}{2} + \frac{1}{2}e^{-2\lambda t} & \frac{1}{2} - \frac{1}{2}e^{-2\lambda t} \\ \frac{1}{2} - \frac{1}{2}e^{-2\lambda t} & \frac{1}{2} + \frac{1}{2}e^{-2\lambda t} \end{bmatrix}.$$

Its stationary distribution  $\pi = [\pi_0, \pi_1]$  is that

$$\pi P(t) = [\pi_0, \pi_1] \begin{bmatrix} \frac{1}{2} + \frac{1}{2}e^{-2\lambda t} & \frac{1}{2} - \frac{1}{2}e^{-2\lambda t} \\ \frac{1}{2} - \frac{1}{2}e^{-2\lambda t} & \frac{1}{2} + \frac{1}{2}e^{-2\lambda t} \end{bmatrix} = [\pi_0, \pi_1].$$

and  $\pi_0 + \pi_1 = 1$ . Solving the equation we have

$$\pi_0 = \pi_1 = 0.5.$$

Stationary and Limiting  
Distribution

In theory, we can find the stationary (and limiting) distribution by solving  $\pi \mathbb{P}(t) = \pi$  and  $\lim_{t \rightarrow \infty} \mathbb{P}(t)$ . However, in practice  $\mathbb{P}$  is usually very complicated.

### Theorem

*The probability distribution  $\pi$  on  $\mathbb{S}$  is a stationary distribution for  $X_t$  if and only if it satisfies*

$$\pi A = 0.$$

## Proof.

For stationary distribution,  $\pi = \pi \mathbb{P}(t)$ , we take derivative on both side

$$\begin{aligned} 0 &= \frac{d}{dt}[\pi P(t)] \\ &= \pi P'(t) \\ &= \pi A P(t) \quad (\text{backward equations}) \end{aligned}$$

Let  $t = 0$ , we have  $\mathbb{P}(0) = \mathbb{I}$ , hence

$$0 = \pi A.$$

The previous simple two state example,

$$A = \begin{bmatrix} -\lambda & \lambda \\ \lambda & -\lambda \end{bmatrix}.$$

Solving

$$\pi A = [\pi_0, \pi_1] \begin{bmatrix} -\lambda & \lambda \\ \lambda & -\lambda \end{bmatrix} = 0.$$

which result  $\pi_0 = \pi_1$ , together with  $\pi_0 + \pi_1 = 1$ , we have  $\pi_i = 0.5$ .
